## *The Impact Factor Fetishism*

### **Abstract**

One of the most popular indicators is the Impact Factor. This paper examines the coming into being of this highly influential figure. It is the offspring of Eugene Garfield's experimentation with the huge amounts of data available at his Institute for Scientific Information and the result of a number of attempts to find appropriate measurements for the success ("impact") of articles and journals. The completely inductive procedure was initially adjusted by examining the data thoughtfully and by consulting with experts from different scientific disciplines. Later, its calculation modes were imposed on other disciplines without further consideration. The paper demonstrates in detail the inopportune consequences of this, in particular for sociology. Neither the definition of disciplines, nor the selection of journals for the Web of Science/Social Science Citation Index follows any comprehensible rationale. The procedures for calculating the impact factor are inappropriate. Despite its obvious unsuitability, the impact factor is used by editors of sociological journals for marketing and impression management purposes. Fetishism!

*Keywords:* Impact Factor; Web of Science/Social Science Citation Index; Eugene Garfield; journals; European sociology; Measurement; Scientometrics.

NEARLY EVERY SOCIAL GROUP HAS ESTABLISHED its own metrics which are used for the practical purposes of evaluation, rating, and ranking. Sports aficionados run their hit statistics; stockbrokers base their decisions on PPR (price-profit ratio); lay people are counseled by offering them everyday life benchmarks: body mass index, IQ and similar numbers inform everyone about their place in the social universe. On the societal level, memorable numbers indicate the well-being of societies: GDP, unemployment rates, divorce rates, etc. The academic world is no exception; its gold standard nowadays is the impact factor (IF). Most of these widely-used indicators are based on very similar trajectories: in the early days, simple counts of units (tax-payers, soldiers and articles) were seen as sufficient, but within a relatively short period of time fractional arithmetic entered the accounting procedure and different key figures have been the result.

No two of these popular indicators follow the same logic. The divorce rate does not cover who officially lived together but were unmarried, the unemployment rate does not take the discouraged workforce into consideration, and the proverbial criticism towards measuring economic well-being by including only monetary exchanges and omitting the shadow market now obtains broader consensus than the knowledge about validity and performance of national accounting systems. Once established, many of these standards were not adjusted to later developments but survived in their original form. Even unanimous rejection by experts who regularly point to the shortcomings and misuse of such numbers has not altered practices (Fleck 2010). The same has occurred with the IF. It is used widely today, critics point to its inadequacies, but as a social routine it works nevertheless. The present paper examines the routines behind the calculation of the IF and its usages.

The thesis of this paper is as follows: the IF has become a widely used and often announced indicator for the alleged quality of journals, first in the sciences and later on also in the social sciences and the humanities. Those who use it seldom point to its shortcomings. A closer look at the procedures of its coming into being reveals several arbitrary decisions which were very quickly accepted besides the ad hoc circumstances of its origination. The result of this aggregation of steps of inductive adaptation was the establishment of what one could label the “IF regime” which forces all disciplines to submit to the reign of a measurement whose appropriateness has been proven only for a small sample of disciplines from the hard sciences. Instead of using sociological competencies to dissect the arbitrary measures, the vast majority of editors and publishers of sociological journals announces the IF for marketing efforts, and sociologists doing comparative analyses use it as a key indicator. A closer look at the calculation of IF demonstrates its almost complete futility. The aim of the present paper is to demonstrate this in detail because up to now almost no one from sociology has devoted attention to the basic decisions behind the IF regime. It is beyond the present contribution to offer an analysis of the practices of the IF regime, something that will have to be reserved for future work. Before starting such an investigation it is necessary to scrutinize IF’s basic features.

The paper starts with a short overview of the present usage of IF. It describes then the coming into being of the IF and points to the unavoidable factors that have laid the ground for the following path-dependency. I then study the IF in more detail and demonstrate its working within sociology, namely for journals from Europe. A closer

look at the production practices of IF numbers reveals an array of unwarranted decisions, shortcomings, and errors. The result of this examination is not only devastating for the originators, but also for those who use key numbers like the IF. Finally I offer some clues as to why the IF has become the gold standard not only in sociology but also here.<sup>1</sup>

*The use and misuse of the IF*

The IF is used widely. Evaluation bodies like the British Research Assessment Exercise (RAE) base their recommendations, at least in practice, on bibliometric measures; the European Research Council requires applicants for its advanced grants to provide data on citations (European Commission 2011: 26); universities increasingly consult citation indexes for decisions about hiring and promotion; and Asian countries have started to pay their scholars per paper published in “elite” journals (Fuyuno and Cyranoski 2006). The *Times Higher Education* World University Rankings base their measurements to a great extent on data from the Web of Science (WoS) which is not really surprising because the World University Rankings is now “powered by Thomson Reuters”<sup>2</sup> – the very same firm that acquired WoS several years ago. The IF became a kind of benchmark for academic affairs, very similar to the indicators of well-being mentioned before.<sup>3</sup>

Given the regular criticisms of measures such as the IF it is even more surprising that sociology journal editors overwhelmingly accept WoS’s IF as authentication for their own achievement. All of the first 53 sociology journals ranked in the Journal Citation Reports (JCR) 2011 announced their most recent IF in one way or another. In some cases the rank within the JCR’s subject categories was added as well.

<sup>1</sup> I do not suggest that sociology is in any way particular but focus on sociology for two reasons: on the one hand it is my own discipline and on the other hand sociologists are trained to scrutinize their data with more care than scholars from other branches of scholarship but do not exhibit this professional strength when it comes to the citation indexing business.

<sup>2</sup> <http://www.timeshighereducation.co.uk/world-university-rankings/2012-13/world-ranking/methodology>, accessed 5 December 2012.

<sup>3</sup> Very often critics are driven by an attempt to reject the basic assumptions behind scientometrics and the impact factor, the possibility of measuring intellectual differences, e.g. Münch (2007) and Collini (2012); for a more detailed critical commentary: Fischer (2008). This paper does not challenge the possibility of scientometrics in general, only the routines of calculating the IF and its utilization. The present author remains agnostic with regard to the probable merits of quantitative analyses of differences between scholars and their products.

The IFs of previous years are rarely made public, but in nearly all cases the announcement of the current IF is highly visible on the particular journals' website.<sup>4</sup> I found only 31 journals which avoided mentioning the IF; not surprisingly, the ranks of these journals were below average.

The University of Chicago Press proclaims on its website that its "journals continue to earn top impact factor rankings", followed by a list of eleven of its journals with their ranks in particular subject fields, and even more propaganda together with an explanation of the IF:

Journal Citation Reports® offers a systematic, objective means to critically evaluate the world's leading journals, with quantifiable, statistical information based on citation data. By compiling articles' cited references, JCR® helps to measure research influence and impact at the journal and category levels, and shows the relationship between citing and cited journals.<sup>5</sup>

Editors are committed to using the IF when their trumpeting adds praise and pride to their performance.<sup>6</sup> For example, the editors of *Ethnic and Racial Studies*, Martin Bulmer and John Solomos, published an editorial in the last issue of 2010 where they announced that "the impact of the journal on the wider scholarly communities has been reflected in the increased Impact Factor we have been awarded in the ISI Social Science Citation Index for 2009, published in 2010" (Bulmer and Solomos 2010, my emphasis). The editor of *Contemporary Sociology*, Alan Sica, recently referred to the "unintended consequences" of the impact factor and the "diminishing status of critical reviewing over the last few decades" in one of his Editor's Remarks, then reported on measures proposed by members of the *Contemporary Sociology* Editorial Board which should result in an increased IF in the near future (Sica 2012: 138). The outgoing editors Wolfgang Streeck and Jürgen Feick even went a step further and told their readers: "In 2012, *Socio-Economic*

<sup>4</sup> Some journals give different additional information, e.g. "European Sociological Review has received an increased impact factor of 1.935, placing it in the top 10% in the field of Sociology." <http://esr.oxfordjournals.org/>. "2010 Journal Citation Reports® ranks *Journal of Mathematical Sociology* in the Mathematical Methods (social science), Sociology, and the Mathematics, Interdisciplinary Applications (science) categories." <http://www.tandfonline.com/action/aboutThisJournal?show=aimsScope&journalCode=gmas20>. "News: The *Economic and Social Review* has been accepted for the Social Sciences Citation Index. More details to follow." <http://www.esr>.

[ie/ESRPage2.html](http://www.esr/ESRPage2.html). "A bibliometric study carried out by the Scientific Department 'Social and Human Sciences' of the National Center for Scientific Research, Paris, published in his Bulletin, n° 69, May 2004, ranked the *Revue Française de Sociologie*, as the leading French Journal with an international audience." <http://www.rfs-revue.com/spip.php%3Frubrique8&lang=en.html>.

<sup>5</sup> [http://www.press.uchicago.edu/pressReleases/2012/July/UCP\\_1207\\_ImpactFactor.html](http://www.press.uchicago.edu/pressReleases/2012/July/UCP_1207_ImpactFactor.html), accessed 29 November 2012.

<sup>6</sup> See for a very different attitude the statement of the editors of about 50 history of science journals Fox *et al.* 2009.

*Review* received its first Impact Factor: we are proud that SER attained a strong 1.78” (Streck and Feick 2012).

Commentators from academia often qualify the usage of the IF as window dressing, fetishism, gaming the game, and myth and ceremony (Meyer and Rowan 1977; Baum 2011; Macdonald and Kam 2007, 2011) etc. Even if one accepts this view as appropriate one can at the same time insist upon the fact that selecting the IF as a benchmark is consequential in itself. Those who devalue the IF on the one hand and use it for whatever reasons on the other contribute to its survival and assign it a status, at least for impression management (comp. Kieser 2010, 2012).

The behavior of ordinary academics has been affected by the booming citation index concert in two ways. Most probably their reading habits are modeled by the ranking itself (Willmott 2011). Any attempt to stay informed is based on the choice of journal one browses through regularly, or consults first in preparation of research or teaching. A self-enhancing circle can be expected that brings papers from the highly consulted journals sooner into the reference lists than papers from journals with minor reputation.<sup>7</sup> Additionally, we try to place our papers in high-ranking journals and obtain the needed information from sources like the JCR, despite our grumbling about the increasing role of what has been called “audit culture” (Power 1997, Strathern 2000, Holmwood 2010).

The IF is, however, not only used for promotion, marketing, and academic distinctions but also as a source for comparing nations’ scholarly productivity. Three otherwise serious publications from different fields of expertise can be used to illustrate this. All of them make use of WoS data without considering the validity of its classification and the consequences of the arbitrary expansion of its coverage. Philip Mirowski (Mirowski 2011) attests a decline of the American science system due to marketization, based on a decreasing proportion of scholarly articles authored by Americans, without recognizing that this might be the aberrant effect of Thomson Reuters’ inclusion policies in its different citation indexes. Since there is no opportunity for this for-profit company to increase the coverage of American journals much further, it can expand the coverage of its indexes only by ignoring once

<sup>7</sup> However, the correlation between the impact factor and the immediacy index (defined as the average number of times an article is cited in the year it is published) in 2011 is only 0.057 and most probably a ran-

dom result. From the top ten journals in 2010 according to the IF only *BJS* and *Annual Review of Sociology* are under the first ten, whereas in 2011 *ASR*, *BJS* and *AJS* are to be found in this range.

established criteria of quality. The fact that there are a huge number of uncovered journals worldwide functions as an incentive for expansion, which could be presented to the audience as a farewell to American parochialism, or imperialism. Any comparative argument based on WoS data is necessarily biased. Evan Schofer (Schofer 2004) uses *inter alia* data from the JCR for his comparison of “nearly 100 nations”, claiming validity because of an allegedly high correlation with other variables, whose composition one cannot prove but which might be similarly problematic – and all his associates from the “world polity approach” continuously do the same.<sup>8</sup> UNESCO’s *World Social Science Report 2010*, claiming to provide analyses of the presumed fact that “Knowledge Divides”, is also not free from ambiguities (UNESCO and ISSC 2010). The portrait of the “world distribution of social science journals” is based not only on WoS but also on Ulrich’s, and Scopus mentions differences between these sources, but then reports that “the picture varies according to the database used, but remains coherent on a global level” (Gingras and Mosbah-Natanson 2010: 150), without considering the possibility that all three sources might contain the same type of bias. One cannot refrain from accusing Mirowski, Schofer *et al.* of comparing apples and oranges.

The number of sociological publications investigating the basic routines of citation indexing is remarkably modest.<sup>9</sup> Beyond the closed circles of scientometricians, once called by one of its founding fathers a “‘relatively’ hard social science”<sup>10</sup>, the interest to do research in this field and to evaluate its merits and vices is minimal, and studies of the social studies of science type are a desideratum.

In the following section I try to provide an analysis of the coming into being of the IF and will then switch to a more detailed analysis of its computation. The trajectory of the IF demonstrates path dependencies.

### *The origins of the Impact Factor*

It is well known that the IF was a spin-off of the establishment of the Citation Index series founded and designed by the entrepreneurial bibliographer Eugene Garfield in 1964, first for the hard sciences, and

<sup>8</sup> Schofer 2004: 240; Drori *et al.* 2003: 196-213.

<sup>9</sup> Aaltojärvi *et al.* 2008; Bjarnason and Sigfusdottir 2002; Persson 1985. Most papers by sociologists deal with practices in the

sciences and make only few remarks on the social sciences: Baldi 1998; Hargens 2000.

<sup>10</sup> Price 1978: 7; Wouters and Leydesdorff 1994, comp. Garfield 1988.

subsequently expanded towards the social sciences and the humanities, in 1973 and 1978 respectively (Bensman 2007). It is less well known that the emergence of the IF was a completely incidental result of Garfield's animus shoveling around the huge amounts of data stored in the then rare mainframe computers of his Institute for Scientific Information (ISI). The most consequential result of Garfield's experimentation was the IF, introduced by him as a term as early as 1955 (Bensman 2007: 111). It is worth examining its emergence in more detail.

### *Mixed motives*

The initial motive behind the creation of citation indexes was the growth in scientific publications, which surpassed the observability of even the most devoted scholarly bibliographers (see Abbott 2011). At the very beginning of indexing, papers' cited references were put into the database to offer users the opportunity of identifying additional relevant papers for their particular research interests. Garfield's ISI appeared on the market of information retrieval at a time when there was a widespread awareness of an increasing inability to cope with the information explosion, a term coined, or at least made popular, at a conference held at the Royal Society in London as early as 1948. The parlance of the exponential growth of publications asked for remedies (see Becker 1968 for a coeval overview) and new devices were established: in 1951, UNESCO founded the International Bibliography of the Social Sciences, which tried to cover international publication output in an old-fashioned way, initially not even using computers. Garfield's Citation Index however, which appeared in five printed volumes in 1963 and reported on what had been published during the year 1961 (initially only covering journals from physics and life sciences), was more than just another attempt to serve academia.

The defects of the then existing bibliographical devices asked for "an effective means of disseminating and/or retrieving scientific literature" (Garfield 1963: 289). In 1955 Garfield thought of single papers whose "significance" or "influence" could be measured by the total number of citations made to them. Already at this time Garfield suggested that the data could be used for "sociological evaluations, including personnel and fellowship selection" if one avoids "promiscuous and careless use" (Garfield 1963: 290). In 1963, Garfield and his co-author I. H. Sher declared that they were "interested in certain 'impact'

factors such as how often a particular paper, author, or journal is cited compared to corresponding average values in a given Citation Index file" (Garfield and Sher 1963: 199). Analyzing the sheer number of citations brought implausible results, because some journals published more papers than others. Garfield therefore suggested "a more sophisticated approach" to measure the impact by dividing "the number of times a journal is cited by the number of articles that journal has published" (*ibid.*: 200). The resulting numbers were a better fit for the expectations of the bibliographers.

When first proposed, the aim of the invention was to establish a rationale for the selection of journals for the Citation Indexes. Instead of avoiding ambiguities they became routines: journals became indexed because they contained a critical number of highly cited papers, even though scientists usually referred not to journals but to particular articles.

### *Different audiences*

The main audience for the establishment of the Citation Index was librarians and their acquisition decisions rather than scholars trying to master the growth of scientific information. Whereas scholars would have been interested in locating relevant publications, librarians had to make up their mind with regard to their acquisition budget and wanted to know which journals they should order. The impact factor was first made public in 1975 when ISI started publishing the Journal Citation Reports (JCR) as an annual supplement to the Science Citation Index (SCI). Its immediate success and widespread recognition were accompanied by promises beyond the provision of a system for information retrieval. Sociologists recognized this from the very beginning: "Another technique [to speed up and increase effectiveness of the dissemination of information in science], facilitated by the use of high-speed computers, is the citation index, which enables one to trace the influence of a given paper forward in time; this will apparently be of value to historians and sociologists of science as well as those concerned with the substantive content of materials cited" (Kaplan and Storer 1968: 116). Both the usability of the SCI and the promise to offer more than just another reference work were crucial for the success of Garfield's one-man-enterprise. After a few years the SCI, the Social Science Citation Index (SSCI), and the Arts and Humanities Citation Index (A&HCI), accompanied by several descendants, such as e.g. the Reference Journal Citation Index, Source Journal Citation Index,

Journal Citation Report, Current Contents and New Scientist, established a monopoly for information retrieval and evaluation. From the very beginning, Garfield played with ideas to make use of the SCI to predict Nobel Prize winners (Garfield 1973, Ashton 1978); he provided help for several kinds of decision makers, and through his usage of an evaluative language (significant, important, core, impact, etc.) ISI's data became more than just data. The IF did not receive much attention during its first three decades;<sup>11</sup> only from the middle of the 1990s onwards did the IF become what it is today: a controversial but highly influential number, trivialized by administrators, and displayed by those who participate in academic impression management.

### *Experimenting with stored data*

Garfield's admiration for science itself disposed him to experiment with data, which resulted in suggestions for several measurements and indicators. His familiarity with debates in the social sciences prompted him to contribute to the then nascent sociology of science. In 1970 he claimed to be part of "a new breed of sociometrist concerned with the historical, sociological, economic, and behavioral study of science and scientists", and labeled them "Scientists of Science" (Garfield 1977b: 158). Due to his own devotion to statistical calculations and encouraged by leading scientists and exponents from the emerging field of sociology of science, Joshua Lederberg and Robert K. Merton, respectively, Garfield experimented with several measures based on the increasing amount of data at hand (Lederberg 2000, Merton 1979, Merton and Garfield 1986, Merton 2000). Over the next decades, Garfield and other authors proposed several indicators, calibrated, designed and re-designed them, but in the end only a few of them were accepted. It seems fair to state that all these indicators were the result of a completely inductive procedure. In nearly all cases they arose from ad hoc decisions.

Using stored data from the field of genetics, Garfield and his collaborators found regularities. First, they recognized that the frequency of citations showed a highly skewed distribution. "A small group of 250 journals provided almost half of the 3.85 million references processed for the SCI in 1969" (Garfield 1972, quoted from the reprint in

<sup>11</sup> Elkana *et al.* 1978, Archambault and Larivière 2009: 636. A simple JSTOR search for "impact factor" in sociology journals resulted in 68 hits only. The first paper

discussing the IF appeared in 1988. During the next two decades between one and five articles were published annually, with a peak in 2007 when nine papers were detected.

Garfield 1977a: 534). Second, this resulted in the creation of the notion of “core journals”: “No matter what the specialty, a relatively small core of journals will account for as much as 90 % of the significant literature, while attempts to gather 100 % of it will add journals to the core at an exponential rate” (Garfield 1971: 5).

Third, details of the calculation of any IF were yet to be established. Back in 1963, the ratio (“number of citations divided by number of papers published”) was suggested with no restriction to particular time periods. Later on, however, Garfield claimed to have found that a restriction of the sample would not hamper the validity, following the findings of two British authors (Martyn and Gilchrist 1968) who had used ISI’s data to evaluate British journals. In 1972, Garfield proposed that “the ratio between citations to particular years of a journal and the number of articles published in those years” (Garfield 1977c: 270) would work just as well as the computation of all citations. Even more consequential was another decision, which again was first proposed by Martyn and Gilchrist, the British duo mentioned above: Garfield found that “about 25 % of all citations are made to the two-year period prior to the source year chosen”. The resulting “current impact factor” intentionally discounted “the effect of most super-classics” (*ibid.*: 271).<sup>12</sup> At this time the SCI covered 565 science journals and about one million citations, and these *ad hoc* limitations were probably not invalidating the results. We will see later that this retrenchment is less plausible for other branches of scholarship, particularly the social sciences and humanities.

Prior to this, one needs to point to a fourth decision which also became part of the definition of the IF business. Garfield and others recognized that particular types of texts, the so-called “reviews”<sup>13</sup> (articles summarizing the literature in trend reports) – which later on became characteristic of publications within the different *Annual Reviews* – were cited more heavily than others: “Garfield came to recognize that the sentences in review articles are implicit indexing statements and that the process of producing a scientific index could be automated by making these sentences the grist for such an index. This idea eventually led to creation of the SCI” (Bensman 2007: 108).

<sup>12</sup> “Super-classics” are highly cited papers whose inclusion would skew the outcome.

<sup>13</sup> Today these kinds of texts are defined the following way by Thomson Reuters: “Review: An item is classified as a review if it meets any of the following criteria: it cites more than 100 references – it appears in a review publication

or a review section of a journal – the word review or overview appears in its title – the abstract states that it is a review or survey”, [http://admin-apps.webofknowledge.com/JCR/help/h\\_glossary.htm](http://admin-apps.webofknowledge.com/JCR/help/h_glossary.htm), accessed 12 December 2012.

## IMPACT FACTOR

Today, Thomson Reuters' computers produce figures that are widely used without looking at the process of their production. According to their help site, the IF as it is computed today is a simple fraction:

The journal Impact Factor is the average number of times articles from the journal published in the past two years have been cited in the JCR year. The Impact Factor is calculated by dividing the number of citations in the JCR year by the total number of articles published in the two previous years. An Impact Factor of 1.0 means that, on average, the articles published one or two years ago have been cited one time. An Impact Factor of 2.5 means that, on average, the articles published one or two years ago have been cited two and a half times. Citing articles may be from the same journal; most citing articles are from different journals.<sup>14</sup>

However, as always, the devil is in the details. What is the “number of citations”? A simple mind would answer: all references in a particular article published in a particular journal count as citations. For practical reasons providers such as Thomson Reuters' Web of Science (WoS) might do the calculation only for a selection of journals, but for every journal covered the computation should work well.

Still, the same simple mind would get into even more trouble with regard to the denominator. “The total number of articles published in the two previous years” obviously will not encompass all 247,854 articles (and “reviews”) collected by Sociological Abstracts (SA) for 2009 and 2010, or the 238,955 articles and “reviews” published worldwide during the same period (in Scopus) but only those 8,869 articles and “reviews” covered by WoS for the same two years. But which journals are knighted this way? Again, one has to accept that an enterprise like Thomson Reuters is not disposed to include other journals than those contained in its database, but only if the policy behind the selection is transparent and sound.

In summary one can see that several ad hoc decisions, which made sense for the particular disciplines and journals originally covered in the Citation Index, became transformed into standards. This execution of experimental calculations was a two-sided elitism, favoring science over other academic disciplines, and paying more attention to journals of unquestionable status compared to all other media of scholarly communication. The results of all this could be adjusted and refined because of the observability of the entire field at this point in time. For Garfield and his highly placed academic supporters the calculations made sense, because they fitted into their picture of the American

<sup>14</sup> [http://admin-apps.webofknowledge.com/JCR/help/h\\_impfact.htm#impact\\_factor](http://admin-apps.webofknowledge.com/JCR/help/h_impfact.htm#impact_factor). A somewhat different explanation can be found

at: [http://thomsonreuters.com/products\\_services/science/free/essays/impact\\_factor/](http://thomsonreuters.com/products_services/science/free/essays/impact_factor/), accessed 12 December 2012.

landscape of science, and he rejected other measurements that did not meet this criterion.<sup>15</sup> In later years, when the Citation Index business expanded to other disciplines and more countries and languages, the already established routines and measurements were imposed on others, which lacked the agency to veto or demand adjustments. Like Goethe's sorcerer's apprentice, Garfield has raised his voice more than once over the last decades to distance himself from the alleged misuse of his invention, but with as little success as the literary counterpart.<sup>16</sup>

It can be argued with some justification that what happened here was the interaction of the self-fulfilling prophecy mechanism with the emerging monopolistic market position of the ISI. Several authors have highlighted the arbitrariness of the IF, and in the following sections I will provide illustrations for three main aspects: the range of the observation period, the definition of disciplines, and the selection of journals.

*Two years are not sufficient, at least not for sociology*

The two-year observation period was established as a consequence of inspecting a set of journals from hard science disciplines, and became the standard for all journals covered in the Web of Science (WoS) and the Journal Citation Report (JCR).<sup>17</sup> Today's journals inherit the burden of these early decisions, but if ISI had studied a different set of disciplines and journals, the result would have been quite different.

One can illustrate this by examining three leading sociology journals (*American Sociological Review*, *British Journal of Sociology* and *Kölner Zeitschrift für Soziologie und Sozialpsychologie*) in order to highlight the practice of sociologists.<sup>18</sup> I coded the list of references from all main articles for two recent issues of each of the three journals. The sample consists of 41 articles with a total of 2,731

<sup>15</sup> Garfield's huge website shows that he experimented widely and one can safely assume that he discarded those indicators that did not obtain the approval of his peers.

<sup>16</sup> E.g. Garfield (2005), where Garfield started his talk with the following: "I had considered as an alternative title for my talk 'Citation Sanity and Insanity – the Obsession and Paranoia of Citations and Impact Factors'.

Others might have preferred 'Uses and Abuses of Impact Factors'".

<sup>17</sup> The wide circulation of the JCR seems to be not only the consequence of its easy usage but also the consequence of Thomson Reuters' pricing policy.

<sup>18</sup> Readers might question the small size of the sample but there is no reason to assume that a larger sample would produce a different picture.

## IMPACT FACTOR

references (1,388 of them to articles), or on average 66 bibliographic entries per article. Only 4 % of the citations were self-references, slightly more in the German journal (5.5 %). There is therefore no need to discuss the frequently raised issue of self-citations here in more detail. Half of the references were to journal articles and the other half to any other sort of literature (books, book chapters, newspaper articles, Internet sources, etc.). The 1,388 cited articles appeared in any journal, whereas the calculation of the IF takes into consideration only those journals that are listed in the SSCI. I did not check how many of the cited journals are not in the SSCI<sup>19</sup>, because another limitation left more dramatic traces: only 11.4 % of all citations were directed towards articles which came out in the two previous years.<sup>20</sup> Even if we enlarge the base to all cited sources the percentage remains the same and is still much lower than Garfield's originally established threshold of 25 % (Garfield 1977c: 271). In disciplines like sociology, the practice of citation is obviously very different from science disciplines, and the calculation of the IF therefore affects only about one-tenth of its references. Several of the 41 articles coded did not even cite a single publication within the two years span so crucial for the WoS. The largest share of references goes to pieces published five or more years earlier, with some differences between the three sampled journals.<sup>21</sup> The only defense in favor of SSCI's routines would be to suggest that this small share of about 11 % might be homogenous enough to produce valid results with regard to the "impact" of publications by sociologists. Given the fact that the IF computed by WoS makes use only of those journals that are covered there the real share of references is even lower; if one assumes that sociologists behave in a similar way to political scientists one could subtract half of the quotations as going to non-SSCI sources.

As the data show, sociologists do not systematically prefer quite recently published articles to older sources. Our debates happen to evolve much more slowly than in hot disciplines such as cell biology. Older papers might finally get the same number of citations, but the discipline's habitual inertia is not recognized by WoS's routines. A generalization from a sample of one-tenth most probably produces biased results.

<sup>19</sup> Chi (2012: 442) reports for political science journals that 53 % of the references pointed to journals listed in SSCI.

<sup>20</sup> See additional data in the online supplementary material.

<sup>21</sup> See table 1 next page.

TABLE 1  
Citation routines in selected sociological journals

Journal	Issues	Articles	Ref/art	Citation within prior 2 years			Total of self-citations	Cited articles	All cited sources	
				Articles	% of cited articles	Others	%			
ASR	77 (4,5)	14	91.2	72	9.2 %	55	42	3.3 %	780	1,277
BJS	62 (3,4)	17	54.2	63	19.1 %	62	35	3.8 %	329	922
KZfSS	64 (1,2)	10	53.2	23	8.2 %	31	29	5.5 %	279	532
Total/Mean		41	66.2	158	11.4 %	148	106	4.2 %	1,388	2,731
<b>Citation within 3 to 5 years</b>										
ASR				154	19.7 %	85				
BJS				69	21 %	73				
KZfSS				51	18.3 %	39				
Total/Mean				274	19.7 %	197				
<b>Citation to &gt; 5 years</b>										
ASR				554	71 %	357				
BJS				197	59.9 %	458				
KZfSS				205	73.5 %	183				
Total/Mean				956	68.9 %	998				

Note: *American Sociological Review* (ASR), *British Journal of Sociology* (BJS), and *Kölner Zeitschrift für Soziologie und Sozialpsychologie* (KZfSS), my calculations.

## IMPACT FACTOR

Several critics and a few defenders of the SSCI argue that there is the alternative of a five-year period of observation, and that the JCR also reports this and other measures. If we look at the five-year indicator, in the case of these three sociology journals the data are still demanding: The (cumulated) share of citations to articles goes up to 31 % (or 28 % if one computes all citations < 5 years to all cited sources). But even this percentage is not represented in the calculation of the 5-year IF (because WoS considers only a selection of journals as its source material) and is in all likelihood lower than the magical 25 % Garfield claimed as sufficient for the computation of a valid measure.

This very simple validity check of SSCI routines is in accordance with what every sociologist knows, but that has been lost in an arena where the IF functions as a benchmark. Obviously the 2 years IF is not a sound approximation for sociology<sup>22</sup>, whilst the 5-year IF would probably work for sociology but is not used by its practitioners. At least the editors and publishers of the vast majority of those journals covered by the SSCI jettison their everyday knowledge and use the IF for marketing affairs.

The observation period is not the only shortcoming of the IF computation.

### *What makes a discipline?*

A second particularity which results in arbitrariness is rooted in the definition of disciplines, especially in the social sciences. The criteria for including particular journals in the SSCI and their allocation to subject categories lack comprehension. The SSCI covers 41 different subjects and one cannot detect the underlying rationale for its composition (the SCI covers about 170 subjects). The social sciences are classified according to classical disciplines, such as anthropology, geography, history, law, political science, sociology, etc. but also include special or interdisciplinary fields of research, like ethnic studies, family studies, gerontology, etc. Psychology, for example, is covered in ten different subfields plus psychiatry whereas economics stands alone. In addition one comes across less well known and well-defined specialties, such as ergonomics, planning & development, rehabilitation, substance abuse, transport etc. All in all some 2,700 journals are included in the

<sup>22</sup> "The use of the 2-year impact factor [...] is one of the most common improper practices" Glänzel and Moed (2002: 312).

database (with 1,000 double or multi entries): 305 from economics, 220 in education, and 608 in the ten subfields of psychology. Other fields are as narrow as "history of social sciences" (27)<sup>23</sup> or "social sciences, mathematical methods" (43), but there are also broad categories like "social issue" with very few journals (35), or in the case of "social sciences, interdisciplinary", with a very large number of journals (84), which is considerably higher than the numbers in more or less established specialized fields, such as "demography" (24), "gerontology" (30), "urban studies" (36), and much less crystalized specialties like "rehabilitation" (64), "transportation" (23) and "substance abuse" (29).

The placement of a particular journal in one of these subjects is contestable. Take for example *Poetics* which is in sociology, *Economy and Society* which is listed both in economics and sociology, whereas *Minerva* is represented in three fields (education and educational research; history and philosophy of science; and social sciences, interdisciplinary; but not in history of social sciences) and *New Left Review* in two (political science and social sciences, interdisciplinary). *Actes de la recherche en sciences sociales* is only in "social science, interdisciplinary" whereas *Human Relations* is there but also in "management". All these classifications might make sense in some way but they hamper any analysis and comparison of disciplines.

The selection of journals for the SSCI does not correlate with the number of scholarly journals in several subjects. Nor do those selected represent the same share of highest recognized journals in each of the subjects. This can be seen by comparing the range of IFs for particular disciplines. For example, the psychological journal with the highest impact factor is *Behavioral and Brain Sciences* (21.9) followed by the *Annual Review of Psychology* (18.3) but the journals on ranks further back than 200 (406 in total) only have an impact factor below 1.8. In Economics the highest ranked journal is the *Journal of Economic Literature* (7.4), but further back than rank 40 the journals reach impact factors smaller than 1.8, all in all 260. The impact factors of the 76 journals from anthropology range from 4.5 down to 0.076, but the level of 1.8 is exceeded only by the first eleven journals. These few examples suggest that the selection process no longer mirrors the initial rationale for inclusion: to cover only journals with a given reputation, by excluding all those that do not surmount a

<sup>23</sup> One gets the impression that journals were placed into this subject by a machine: If "history\*" is in the title, put it into subject "history of social sciences". Jour-

nals like *History of the Family* and *Business History* neither belong to the field of history of social science nor have anything else in common.

(pragmatically defined) threshold.<sup>24</sup> Any comparative research for the subfields of the social sciences ends inconclusively. For the 41 social science subunits the (median) impact factor ranges from 1.8 for “psychology, biological” down to 0.3 for “cultural studies” and history.<sup>25</sup>

Whether a particular journal is covered at all should be the consequence of its high reputation, measured by citations. It is fair, however, to remind readers that nowadays the owner of WoS, Thomson Reuters, selects journals not only because of their “reputation” but also for other reasons, as they frankly declare on their website:

All social science journals undergo the same thorough evaluation as journals in the natural sciences. Publishing standards, editorial content, international diversity, and citation data are all considered. Standard citation metrics, at both journal and author levels, are analyzed while keeping in mind that overall citation rates in the social sciences are generally lower than those in the natural sciences. Regional studies have special importance in the social sciences, as topics of local rather than global interest are often the subject of scholarly research (Testa 2012).

The haphazard decision about the inclusion of particular journals in arbitrarily confined pseudo-disciplines (“subject categories”) obviously influences the calculation of the IF, even more emphatically when the numbers (of articles and citations) are small.

### *European sociological journals in the SSCI*

Data from WoS, published in JCR, do not only impress different groups of users but were used for international comparative research as we have seen before. To further demonstrate the inappropriateness of the SSCI for any analysis of national productivity or similar topics let us consider in detail the representation of European sociological journals in it. Since there is no way to establish the phenomenon “European sociology” correctly because of the lack of data at hand,

<sup>24</sup> The original rationale for covering only the highest ranking journals was based on particular “laws”: on the exponentially diminishing returns of extending a search for references in science journals (Bradford’s law of scattering), on the number of authors publishing a certain number of articles as a fixed ratio to the number of authors publishing a single article (Lotka’s law), and “Garfield’s law of concentration”. The message of all these distribution patterns was, and still is, that any bibliometrics can be restricted to a core of highest ranked units.

<sup>25</sup> One should remind the non-specialized reader that in the sciences the range is much wider, both for the mean and the single year impact factor. The mean is 2.34 for biochemistry and 0.58 for mathematics, and the highest ranked journals reach a yearly impact factor as high as 32.406 for *Cell*, whereas the highest ranked SSCI journal, *Behavioral and Brain Sciences* reaches 21.952, the *Journal of Economic Literature* (rank 11) has an IF of 7.432 and the highest ranked sociology journal, *American Sociological Review*, is on rank 91 with an IF of 3.693.

authors have to rely on databases such as CSA Sociological Abstracts (SA), Scopus, WoS and sometimes Ulrich's Periodicals Directory for their analyses. Whereas ProQuest's SA covers as many journals as possible<sup>26</sup> – and also other kinds of documents – the two more selective databases from Elsevier and Reuters Thompson also provide statistical data on their holdings. Restricting the search in SA to authors' affiliation in larger Europe results in a total of about 10,000 articles published in a single year. The SSCI is remarkably more selective and only provides in the subject category "sociology" data for 4,370 articles and 108 "reviews" annually. Scopus covers the broader field of "social sciences" 125,000 articles and reviews (all data are for 2010).<sup>27</sup>

All three databases offer search options to characterize the European sociological landscape in more detail; at the same time these three sources provide very different portraits of this branch of scholarship. The SSCI and its accompanying Journal Citation Reports (JCR) make it possible to sample journals both by discipline and country of publication.<sup>28</sup> 142 journals are listed there as belonging to "sociology" in 2010 and 17 European countries host 59 of them, allegedly.<sup>29</sup> Some journals are classified as belonging to "sociology" only in addition to other fields of research (ranging from "hospitality, leisure, sport and tourism" to more familiar specialties such as anthropology, linguistics, economics, etc.); if one excludes the journals with two, three or even four classifications and restricts the selection to journals whose first and only "subject category" is "sociology", the number would go down to 36 journals of alleged European provenance.

A case-by-case check brought strange results: In practically all cases the ostensible "country of publication" was indeed the location of the publishing house. For instance the *Journal of Sociology* is indicated as being located in England only because its publisher Sage is, whereas the editors are located down under and the journal is nothing less than the official journal of The Australian Sociological Association (TASA).

<sup>26</sup> According to SA's website: "over 1800 serials, over 40 % of titles are published outside North America" with a scope of coverage to all sub-disciplines of sociology and selected "content from such other disciplines as anthropology, social psychology, demography, education, criminology, penology, and political science."

<sup>27</sup> An obvious shortcoming results from the inability to say anything comprehensible about the book production of sociologists. Engels, Ossenblok and Spruyt (2012) provide

data for the Flemish universities in Belgium. For a particular period under investigation they found 3,000 articles, 123 book chapters, 10 edited books, and 7 monographs in sociology. See also: Ward (2010).

<sup>28</sup> Other bibliometric reports from Thomson Reuters, such as *Essential Science Indicators* or *Journal Performance Indicators*, could not be used for this analysis due to unavailability.

<sup>29</sup> See Table 2 in the online Supplementary material to this article.

Scrutinizing all journals' websites revealed that it is impossible to assign a nation state to each of them. Whenever the group of editors assembled scholars from more than one country, I moved them to the "international" group, in sum 37.<sup>30</sup> The alleged "nationality" of the journals changed dramatically in some cases, in particular the United Kingdom and the Netherlands lost many, whereas the number of journals located in the United States went down only slightly.

As we have seen, Thomson Reuters follows a mixed strategy with regard to the selection of journals for its WoS database. The obvious result for sociology is that the 140+ journals belonging to "sociology" surely include the most prominent exponents, but arbitrariness rules below the top 20. The Polish journals *Eastern European Countryside* (2010 IF 0.053), the Lithuanian *Filosofija - Sociologija* (2010 IF 0.179) and the Vienna based *Innovation - The European Journal of Social Science Research* (2010 IF 0.326) should not be considered as belonging to the core of European sociological publications, at least not as long as others of comparable reputation are excluded, or covered in other less visible subject categories.

The increasing inclusion of journals from former Soviet Europe after 1989 in the SSCI have skewed the overall picture: 59 European journals are included in the SSCI. 17 of them have editors located in the UK, 5 in Germany, 3 in Poland, 2 each in Croatia, France and Spain, and 1 each in Belgium, the Czech Republic, Denmark, Ireland, Lithuania, the Netherlands, Norway, Romania, the Russian Federation, Slovakia, Sweden, and Switzerland. That is, a total of 9 in former Western Europe and 8 from former Soviet Europe, which seems to be in accordance with the number of nation states, but not with regard to population numbers and also not with regard to the number of sociologists. However, there are no data at hand concerning the number of sociologists in Europe. Rough estimates can be drawn from the number of national sociological associations represented either in the European Sociological Association (ESA) and/or in the International Sociological Association (ISA), which is 33. Extrapolating the mean number of sociologists per 100,000 inhabitants from those countries where reliable data are available (n=16), the result would be a minimum of 14,000 sociologists in Europe. This estimate would put Europe on par with the US<sup>31</sup> If we assume that the numbers for

<sup>30</sup> For instance *Theory and Society*, *Poetics*, *Discourse & Society*, *Qualitative Research*, *Acta Sociologica*, *European Sociological Review*, etc.

<sup>31</sup> Kirchner (2004) gives the number of ASA members as 13,000, The Europa World of Learning 2012 has 14,000 and ASA's website claims the same size.

sociologists in Europe and the United States are roughly the same and the institutionalization of sociology in both regions shows a similar stage of development, we could, following the clue of Andrew Abbott<sup>32</sup>, expect a comparable number of sociological journals on both sides of the Atlantic. A search in Ulrich's confirmed this assumption: the 538 journals classified as belonging to sociology are distributed evenly between Europe (244), and North America (US and Canada: 221).<sup>33</sup> Scopus, WoS/JCR and Ulrich's classify the country of publication primarily by using the location of the publishing house. Therefore many more journals are assigned to the Netherlands and the United Kingdom, while several European countries are missing entirely, *e.g.* Bulgaria, Greece, and Portugal. Others, like Italy, are definitely under-covered.

A comparison of publication output will result in a less persuasive picture. Scopus offers data for regions from where "citable documents" originate. For the first decade of the 21<sup>st</sup> century, 93 % of those were published by journals located in Western Europe and less than 7 % in Eastern Europe. However one should keep in mind that the assignment of nations to journals is highly contestable, as mentioned above. Since there are no indications that sociologists from former Soviet Europe produce much better articles than their counterparts in the old West, one has to suspect that Thomson Reuters follows a marketing strategy rather than a professed scholarly excellence. In order to conquer the market of the transformation countries, this for-profit enterprise was driven to please the presumed purchasers of its service.

The erroneous assignment of countries to journals has serious consequences because practically all authors publishing on the international development of scientific productivity, on changing patterns in the competition between nations or the alleged decline or rise of regions, states, the European Union, etc. build their conclusions on data from WoS.

WoS' widely used rhetoric of core, recognition, impact, etc. collides with journal selection practices that are anything but persuasive.

<sup>32</sup> Abbott (2011) estimates that for approximately every 150 scholars a new journal is founded.

<sup>33</sup> Ulrich's (<http://ulrichsweb.serialssolutions.com>). The remainders are from Australia and New Zealand (28), Asia (20), South America (20) and Africa (5). Accessed: May 2013.

*The insignificance of the impact factor*

The JCR provides several key figures for the journals covered. The IF and the 5-year impact factor are the two most frequently used indicators, and the latter is usually higher than the first. The sociological journal with the highest 5-year IF is the *American Sociological Review* (2010: 5.8; 2011: 5.7; compared with a 2-year IF of 4.4 in 2011), followed by the *American Journal of Sociology* (2010: 5.1, 2011: 3.1; 2-year IF in 2011: 3.2), and the *Annual Review of Sociology* (2010: 5.03, 2011: 5.8; 2-year IF in 2011: 4.4). At rank 8 follows the first European journal, the *British Journal of Sociology*, with 2.8 in 2010 (2011: 2.1, 2-year IF in 2011: 1.7).

If one computes the mean of the 2-year IF over a longer period of time (2000 to 2011) the results are enlightening: Again, the journal with the highest mean is *American Sociological Review* with 3.2, followed by *Annual Review of Sociology* with a mean of 2.9 and the *American Journal of Sociology* with 2.8, but the next 10 show only very slight differences, ranging from 1.78 to 1.39. Further down the list the differences almost disappear: Rank 14 to 32 is within the range of 1.387 to 1.024. From rank 33 onwards the 12-year-mean is below 1.<sup>34</sup>

In other words, the average article published in one of the 4 highest ranked journals is cited on average 3 times. The next 28 journals' contributions obtain a resonance equal to 1 citation per year, and the remainder of the 100+ journals covered in the SSCI obtain less attention than 1 citation within the 2-year observation period.

As a further illustration of the capriciousness of the SSCI's established routines one could execute the calculation of a slightly different IF. "Officially" it is the fraction of the "cites" in a given year to items published in the two previous years by the number of items published in these two years. The "cites" come from those "citing journals" which are in the SSCI and the result is the 2-year IF. Given the slowness of sociologists to pay tribute to papers of others it would be justified if, instead of looking for the immediate preceding two years, one was to go back one additional year. To calculate this more appropriate IF (still for any given year) one would then count the "cites" from year 1 to the years -2 and -3, instead of -1 and -2. The three arbitrarily selected nationally leading journals occupy sufficiently different ranks in the SSCI

<sup>34</sup> If one ignores the arbitrary computing of IFs with four digits and rounds the IF to one digit only, the result is telling: whereas the first three ranks are occupied by the above

mentioned well known journals, rank 5 and 6 are occupied evenly by 3, rank 7 by 6, rank 8 by 7, rank 9 by 4, rank 10 by 2, and rank 13 by 13 – all in all covering 42 different journals.

to allow generalizations: Over the 12 year period, *ASR* is ranked #1, *BJS* is ranked #13 and the German *Kölner Zeitschrift* is ranked #67 (out of 148 journals covered). This minor modification results in a much higher IF for *ASR*, and a steadily higher IF for *BJS*, but did not improve the IF of the *Kölner Zeitschrift*, probably because of the overall smaller number of “cites”.<sup>35</sup>

In each year, only a very small share of citations is devoted to papers from the immediate previous year for any of the three journals listed here (and one can generalize this pattern with some justification to all other sociology journals).<sup>36</sup> To illustrate this, we can take the numbers for *ASR* in 2008 as an example: the official IF divides the sum of the number of times articles published the two previous years 2007 and 2006 were cited (86 and 230) by the number of items published in these two years (42 and 42) which is 3.762. Just by going back one further year in the observation period, the result is much more in accordance with the overall distribution of citations:  $230 + 252 / 42 + 41 = 5.807$ . Because of the completely ad hoc approach of those who created the IF, an adaptation which is in accordance with the overall distribution of data over time should not only be allowed, it should be technically mandatory.

ISI's competitor Scopus now computes its own “impact factor” (González-Pereira, Guerrero-Bote und Moya-Anegón o. J.), and we do not want to scrutinize it in the same way as the more established indicator. However, we do wish to mention that for the 86 journals covered in both databases, the Pearson correlation between the 5-year impact factor and the journal ranking indicator of the competitor Scopus, SCImago Journal Rank (SJR), is 0.582 (significant at the 0.01 level). We take this as an additional piece of evidence arguing against the use of impact factors as valid measures for scholarly quality, at least not in sociology.

### *Problems with data reliability*

If one checks the JCR of individual journals, one comes across missing data for the 5-year IF, but can find the raw data to calculate it by using what the JCR is offering at each journal's site. The result is astonishing. For example, for the 5-year IFs: the *Journal of Consumer Culture* would outstrip the prominent American journals with a 5-year IF of 7.13, and the *European Journal of Social Theory* with its 3.33

<sup>35</sup> This is in accord with a pragmatically introduced threshold for the 2-year IF, where factors below 1.8 are considered insignificant.

<sup>36</sup> See Table 3 in the online Supplementary material to this article.

would surpass the *BJS*. Why does Thomson Reuters omit particular data? The seemingly obvious answer that they excluded the 5-year impact factor because of a lack of data either for the “cites” or the “number of published items” is not true: other journals with similar gaps in their data are listed with their 5-year impact factor, e.g. *Eastern European Countryside* and *Current Perspectives in Social Theory*. Most probably Thomson Reuters eliminated the data because their announcement would obviously contradict the expectations of their users: it cannot be the case that a fringe journal such as the *Journal of Consumer Culture* is doing so much better than the established *ASR* and *AJS*. But can we then trust Thomson Reuters with regard to whatever else they deliver?

I used the Social Science Citation Index (SSCI) to retrace the numbers for citations and published articles for several journals and the result is remarkable: the JCR data are nearly irreproducible from the source database SSCI.<sup>37</sup> I tried to reproduce them manually but encountered difficulties with regard to the search options. The most relevant mismatch is the so-called timespan. The IF calculates the fraction “cites to recent items/number of recent items” for a single year only (“cites in [year]”), but the latter cannot be formulated as a search option in the SSCI.<sup>38</sup>

In contrast, a closer look at the data behind the numbers published in the JCR reveals interesting additional information. Let us use the Russian *Sotsiologicheskie Issledovaniya* (roughly Sociological Studies) as an illustration: This journal is covered by the SSCI at least since 2000, its IF is given for 2010 as 0.147 and the 5-year impact factor as 0.135, rank 119 and 93 respectively (the mean IF for the 12-year period is 0.144). Articles and reviews published in 2010 (in journals covered by the SSCI) included 64 citations to articles and reviews that were published in *Sotsiologicheskie Issledovaniya* in the two previous years 2008 and 2009. In the same two years, this journal published an

<sup>37</sup> I am not the first to claim this inconsistency. In *Scientometrics*, a specialized journal, covered in SSCI under the subject “Information science & library science” (IF 1.9), one comes across several critical articles but they seldom find appropriate resonance outside the closed circle of bibliometricians. See e.g. Glänzel and Moed (2002) and Archambault and Larivière (2009). A recently published paper referred to a large number of pros and cons: Vanclay (2011). The most revealing criticisms are: Ingwersen (2012), Moed *et al.* (2012), Pudov-

kin and Garfield (2012), Smith (2012), and Zitt (2012).

<sup>38</sup> In May 2012 I executed the following search: “Cited Work=((journal title)) AND Cited Year=(2005-2009). Refined by: Document Type=(ARTICLE or REVIEW). Databases=SSCI. Timespan=2000-2010” and did the same for “cited year=(2008-2009)”. Later the same year it was not possible to reproduce the searches, because WoS changed the search options for the “timespan” with the consequence that JCR data cannot be reproduced manually.

astonishing total of 436 articles and reviews. 64 divided by 436 results in 0.147. Scrolling down on the website where this information can be found, one can click on a link that brings us to the “cited journal data table” with the “number of times articles published in 2010 (in journals below) cited articles published in SOTSIOL ISSLED+ [this is the acronym used by ISI] (in years below)”. There, one can detect that 47 of the 64 citations appeared in the very same journal. A self-citation rate of 73 % is an enlightening finding, to say the least. In the early years of the citation index business some experts suggested that all self-citations should be excluded from the computation of the impact factor. Later on they established the arbitrary threshold of one-fifth, and found that about 18 % of all journals demonstrate a self-citation rate above this threshold.<sup>39</sup>

The obvious conclusion would be to exclude journals whose self-citation rate is too high (irrespective of where one draws the line) from the reporting, but unlike the cases of those 5-year IFs, which were too high and thus had to be eliminated from the report manually, the distorting numbers located at the bottom of the ranks do not prompt Thomson Reuters to act.

Summarizing the major findings of this study I would like to draw attention to the following shortcomings of the citation indexing business and its flagship, the IF. They can be divided into two groups: deficits intrinsic to the procedures, and shortcomings significant for sociology in particular. The following criticisms do not imply that the whole WoS business is worthless, but that the production and dissemination of professed indicators such as the journal IF are contestable.

1. The IF fraction has been developed inductively by using data from the hard sciences. No rationale for this particular formula has ever been offered, its diffusion is an intended side effect of its stubborn use, and after a while (nearly) everybody accepted it as a valid measure. The predominant inductivism is demonstrated by the regular proposition of new indicators.<sup>40</sup> Above all, the two-year “citation window” is haphazardly chosen and may be applicable only in well-integrated fields of research with a high degree of shared consensus about what research questions will be addressed next.
2. The criteria for what counts as a citable document and which documents are called into play as sources for citations are anything

<sup>39</sup> Vanclay (2011) summarizes these debates in his Table 2.

<sup>40</sup> See Pendlebury (2009) for a recent overview. For an outsider some of the contributions by bibliometricians look like parodies. See e.g. the “Proceedings of 17th

International Conference on Science and Technology Indicators” Archambault, Gingras und Larivière (2012) in particular the paper by two leading scientometricians Glänzel and Moed (Glänzel *et al.* 2012).

but well-defined. The incongruence between numerator and denominator (a larger share above the line for citations and a smaller below for published items) operates as an invitation to abuse; for instance by publishing editorials (a non-citable type of document) with a huge number of self-citations (because WoS does not apply the same restrictions to the origins of citations).

3. The measurement is highly “reactive”, and increasingly so. Authors, editors, publishers and other interested parties model their own behavior to influence the outcomes of bibliometric measurements. Its objectivity is at risk: supposed citation cartels, slicing reports into “least publishable units”, honorable authorship, and similar social techniques of scholarship are known even to those who never enter the field of scholarly publications. Codes of ethics and comparable provisions prove that deviant behavior exists, but its scope is still contested.<sup>41</sup>
4. Since the WoS originated in the US, its coverage of non-American sources is still disputable, especially in disciplines lacking a well-defined cosmopolitan research agenda. Furthermore the decision about the inclusion of journals is opaque, to say the least. Even the founder of ISI, Eugene Garfield, acknowledges that it is a mixture of what he calls “quantitative and qualitative considerations”:

(C)itation data, journal standards, and expert judgment [...] These citation data are a source of quantitative indicators that can be used to evaluate existing journals with established track records. But the selection of journals often relies on other, more qualitative considerations. Journal standards are an example. A journal’s ability to meet its declared schedule and frequency is perhaps the most basic expectation. [...] editorial requirements for abstracts, titles, and references [...] Peer review of submissions, editorial board membership, and the reputation of the publisher [...] are other indicators of journal quality (Garfield 1990: 185).

After the sale of Garfield’s ISI the inclusion policies became even more driven by factors beyond the alleged criteria of measuring the merit of examinees.

In case of the social sciences some additional peculiarities distort the adequacy of the WoS routines:

1. The subdivision of the entire field is unwarranted. Disciplines of comparable status and development, such as economics and psychology, are represented highly unequally; no one could argue that psychology is double the size of economics, and it is also disputable that sociology is only half the size of economics. The broadening of the whole field by including particular applied

<sup>41</sup> A recent article shows the worrying extent of coercive citation patterns: Wilhite and Fong (2012), supporting online material:

[www.sciencemag.org/cgi/content/full/335/6068/542/DC1](http://www.sciencemag.org/cgi/content/full/335/6068/542/DC1).

disciplines and outlandish specialties, such as ergonomics, substance abuse, and transport, leads to the result that the population from where citations might come is autocratically hedged in.

2. Given the lower level of an internationally agreed research agenda in the social sciences, often called fragmentation, the selection of journals is obviously more difficult and contestable at the same time. As a matter of fact, WoS's selection does not follow any of their alleged principles, but implements the market capture strategies of the present owner, Thomson Reuters. Even according to their own standards the vast majority of covered journals should not be regarded as eligible for inclusion.<sup>42</sup>
3. The scholarly practices of sociologists, and probably also of other social scientists, are not mirrored by the arbitrary routines with regard to the "citation window". One only needs to browse any of our journal articles' lists of references to observe that the vast majority of citations is beyond the two-year period crucial for the calculation of the impact factor. This already highly inductive criterion contradicts the routines of disciplines dissimilar to those in the hard sciences and should not be used.
4. The often bemoaned "methodological nationalism"<sup>43</sup> is one more particularity of the social sciences and of sociology in particular. A consequence completely ignored by citation indexing is that sociologists from smaller countries are necessarily hampered in obtaining a comparable amount of recognition via citations. Even those journals that switched to English as their preferred language cannot overcome this restriction. Similar considerations apply for differentiated research specialties: in many cases the number of co-workers is much lower compared to more fancy specialties or areas with stronger international links.

The outcome of several days of data mining is, frankly, that the whole impact factor business proves Karl Marx's findings on commodity fetishism from a long time ago:

There is a physical relation between physical things. But it is different with commodities [...] There it is a definite social relation between men, that assumes, in their eyes, the fantastic form of a relation between things. In order, therefore, to find an analogy, we must have recourse to the mist-enveloped regions of the religious world. In that world the productions of the human brain appear as independent beings endowed with life, and entering into relation both with one another and the

<sup>42</sup> Two-thirds of the journals in economics, 42 % in family studies, 38% in sociology and substance abuse and 35 % in all fields of psychology show an IF lower than 1.0; and yet they are put in the shade by history

journals, where only one has an IF higher than 1.0 and 97 % do not.

<sup>43</sup> First introduced by Martins (1974) and Smith (1983). Compare Wimmer and Glick Schiller (2003).

human race. So it is in the world of commodities with the products of men's hands. This I call the Fetishism which attaches itself to the products of labour, so soon as they are produced as commodities, and which is therefore inseparable from the production of commodities. This Fetishism of commodities has its origin [...] in the peculiar social character of the labour that produces them.<sup>44</sup>

The quite recently established regime of IFs is driven by the business concerns of two international corporations, Thomson Reuters and Elsevier, and accepted as the gold standard in today's academic market by the newly emerging elite of university administrators and policy makers, using it whenever it fits their impression management strategies.

## Résumé

L'un des indicateurs bibliométriques les plus utilisés est le facteur d'impact. On retrace ici l'ascension de ce chiffre si influent. Il est le produit d'une expérimentation d'Eugène Garfield à partir de l'énorme masse de données de son « Institute for Scientific Information » après de nombreux essais pour trouver des mesures convenables de succès (impact) d'articles ou de revues. La démarche, totalement inductive a été d'abord affinée à la fois par l'examen attentif des données et l'appel à des experts scientifiques de quelques disciplines. Par la suite les modalités de calcul ont été étendues aux autres, sans plus de précaution. L'article expose dans le détail les conséquences catastrophiques en particulier pour la sociologie. Ni le contenu des intitulés disciplinaires, ni la sélection des revues dans le Web of Science/Social Science Citation Index ne répondent à des critères rationnels. Il en va de même de la procédure de calcul des facteurs d'impact, qui, en dépit de ces défauts évidents est utilisé par les éditeurs de revues à des fins de marketing et de pilotage. Fétichisme !

*Mots clés:* Facteur d'impact ; Web of Science/Social Science Citation Index ; Eugene Garfield ; Revues ; Sociologie européenne ; Mesures ; Bibliométrie.

## Zusammenfassung

Der Beitrag untersucht Entstehung und Verwendung des "Impact Faktors". Er war ein Nebenprodukt von Eugene Garfields Experimentieren mit den riesigen Datenmengen, die seinem Institute for Scientific Information zur Verfügung standen, um den Erfolg („impact“) von Artikeln und Zeitschriften zu messen. Der Impact Faktor wurde völlig induktive anhand der Daten einiger weniger naturwissenschaftlicher Disziplinen und nach Konsultationen mit Experten aus diesem Bereich entwickelt und danach ohne weitere Prüfung auf andere Disziplinen übertragen. Weder die Definition der Disziplinen, noch die Auswahl der Zeitschriften, die in das Web of Science bzw. den Social Science Citation Index aufgenommen wurden, folgen einer nachvollziehbaren Begründung. Trotz offensichtlicher Ungeeignetheit für die Soziologie wird der Impact Faktor von Herausgebern und Verlagen für Werbe- und Marketingzwecke verwendet und beeinflusst das Leseverhalten und die Veröffentlichungspraktiken von Soziologen. Ihr Verhalten gleicht dem Fetischismus, der vor langem als Merkmal der kapitalistischer Produktionsweise identifiziert wurde.

*Schlagwörter:* Impact Factor; Web of Science/Social Science Citation Index; Eugene Garfield; Zeitschriften; Europäische Sociologie; Messung; Scientometrie.
